[Parry-Romberg syndrome: A case report of non-invasive treatment](#)

Parry-Romberg syndrome is an uncommon condition, self-limiting with slow progressive hemifacial atrophy. This syndrome can lead to several progressive congenital and developmental deformities. It can cause severe facial asymmetry and subsequently lead to esthetic and psychological problems and adversely affect patient's quality of life, so its treatment holds great importance. Still, there is no exact treatment protocol for this disease, treatment approaches are bounded and patient's response to the treatment is imponderable. However, most of the patients can benefit from conservative treatments. In this paper, we have reported a moderate case of Parry-Romberg syndrome, with no familial history of any syndromes. We also have discussed about present anomalies and the steps of exerted conservative treatments.

[The Pierre Marie-Sainton syndrome: Report of a family](#)

Pierre Maria and Sainton syndrome or cleido-cranial dysplasia (CCD) is a rare syndrome presenting an autosomal pattern of inheritance, characterized by characterized by a triad: clavicular aplasia, delayed ossification of the fontanelles and sutures of the vault of the skull. To these may be added multiple dental inclusions.

[Assessment of the effect of cigarette smoking on the different denture base material](#)

Background: The present study was conducted to assess effect of cigarette smoking on different denture base material.

Materials & Methods: The present study was conducted in the department of Prosthodontics. A total of sixty wax specimens in the shape of circular discs were prepared. These were divided into two groups. Group I (30) specimens were heat-cured denture base materials and group II (30) specimens were flexible denture base materials. Both specimens were further divided into four subgroups of 15 each. Subgroup I was heat-cured denture base material specimens (control group), subgroup II was flexible denture base material specimens (control group), subgroup III was heat-cured denture base material specimens exposed to cigarette smoking (study group) and subgroup IV was flexible denture base material specimens exposed to cigarette smoking (study group). The initial (IRa) and final (FRa) surface roughness was measured before and after smoking test of the specimens.

Results: It was observed that in group I, mean IR ( $\mu\text{m}$ ) value was 0.182 and FR value was 0.572. In group II, mean IR ( $\mu\text{m}$ ) value was 0.265 and FR value was 0.831. In group III, mean IR ( $\mu\text{m}$ ) value was 0.195 and FR value was 1.892. In group IV, mean IR ( $\mu\text{m}$ ) value was 0.291 and FR value was 1.892. The difference was significant ( $P < 0.05$ ).

Conclusion: The surface roughness of the specimens fabricated from the flexible denture base material was found to be more compared to heat-cured denture base specimens after exposure to cigarette smoke. There is need to educate the patients regarding cleanliness of denture to avoid infection in the oral cavity.
